Welcome to the Ticket Booth!

The goal of the app is to make ticket and volunteer management for community events easier and automated.

Development Environment Setup

The following walks through a local setup on OS-X M1.

Streamlined Setup

If you installed Homebrew on your laptop, you should be able to boot the app.

Optional VIM and PostgreSQL Local Configuration

We provided a pretty comprehensive VIM configuration with auto-complete, as well as the psql configuration with a prompt and additional useful macros.

To install this, run

bin/install-dev-tooling

After that, your vim sessions will have auto-complete enabled, and your psql -U postgres sessions will have rich prompt.

Running App Dependencies Installer

You can run the following setup script to attempt a complete set up of the development environment, as well as the installation of the Rubies, Gems and Database:

bin/boot-up

This should automatically open the browser at the http://localhost:3000 URL, if all the steps succeed.

The bin/boot-up script will start the Rails server, or show an error that needs to be fixed.

After you stop it with Ctrl-C, you can restart the server using the following shortcut:

make dev

This actually starts Foreman via bundle exec foreman -f Procfile.dev — this is required to start CSS and JS just-in-time compilcation in addition to the Rails server.

Running rails s is no longer sufficient to start the application.

Running Tests and Linters

To verify that your local environment is working, run the following:

This will run DB Migrations, followed by RSpec, Rubocop, and ShellCheck.

Additional Information

We dedicated a separate document to the developer setup, which helps you get the application running locally.

Alternatively, keep reading for step-by-step manual instructions.

Optional Manual Setup

If you prefer to run all the steps manually, then follow the guide below.

Manual 1: Services

Please make sure you have PostgreSQL and running locally, or install it via Homebrew:

```
brew install direnv

brew install postgresql@16
brew services postgresql@16 start

brew install memcached
brew services memcached start
```

Manual 2: Direnv Setup

Before you can start the Ruby Server, you need to configure direnv so that the environment in the file .envrc is loaded on OS-X.

To do that follow the instructions for setting direnv on bash or zsh depending on what you are running. To find out, run echo \$SHELL.

After you setup the shell initialization file, restart your terminal or reload the shell configuration.

Once you are back in the project's folder, run:

```
direnv allow .
```

This will load the environment variables from the .envrc file.

Manual 3: NodeJS & Votal Setup

Run the following to get Volta Node Manager working:

```
curl https://get.volta.sh | bash
volta install node@lts
volta install yarn
volta pin node yarn
```

Now your Node & Yarn should be installed.

Manual 3: Ruby Setup

```
# install brew from https://brew.sh
brew bundle 2>/dev/null

# ensure the following packages exist
brew install rbenv ruby-build direnv volta

eval "$(rbenv init -)"
  eval "$(direnv hook ${SHELL/*\/})"

direnv allow .

rbenv install -s $(cat .ruby-version)
rbenv local $(cat .ruby-version)

bundle install -j 12
rails db:prepare
rails db:test:prepare

# Run Specs at the end:
  bundle exec rspec --parallel
```

Manual 4: Starting the Server

To start the server post-setup, run the following (NOTE: you must start the server via Foreman, since it also starts yarn tasks that monitor and dynamically recompile CSS and JS assets)

```
bundle exec foreman -f Procfile.dev
```

You can also use the Makefile:

```
make dev
```

Here is an example:

```

```

Tooling

Adding Site Admin

When the database is completely blank, the first step is to create the initial account. Lets say you registered as 'kig@fnf.org':

The second step is to make that person a site admin:

```
RAILS_ENV=production
bin/site-admin add kig@fnf.org

# Or, to remove site admin from a given user:
bin/site-admin remove kig@fnf.org
```

Generating Music Submissions List

The repo contains a convenient script for generating HTML to embed into the Wordpress site, using a CSV generated out of Google Spreadsheet collected using Google Forms.

The CSV must contain three columns and a header row:

- DJ Name
- Full Name
- Set URL

To generate the HTML (we'll use the CSV file checked into the fixtures):

```
# eg, using the fixture file:
$ bin/music-submission-links spec/fixtures/chill_sets.csv > chill_set.html

# or, to include the simple CSS into the header:
$ bin/music-submission-links spec/fixtures/chill_sets.csv --simple-css > chill_set.html
open chill_set.html
```

If you add --simple-css to the arguments, the generated HTML will include <head> element with the Simple CSS Stylesheet. Do not use this flag if you plan to paste the output into the WordPress text box. Use this flag if you simply want to verify the resulting HTML in a browser by running open chill set.html.

To verify that the script is working and generating correct HTML, you might want to install a handy tool called bat, eg using Homebrew on Mac OS-X:

```
$ brew install bat
$ bin/music-submission-links spec/fixtures/chill_sets.csv | bat
```

Adding Submissions to WordPress

Now you can open WordPress, create a two-column layout on the submissions page and paste the contents into one of the two columns, typically:

- 1. Night time / Peak Hour
- 2. Chill / Daytime

First, let's copy the resulting HTML into clipboard:

```
$ bin/music-submission-links chill_sets.csv | pbcopy
```

Now we can paste it into WordPress directly.			

API Documentation

Yard-generated documentation is available via running:

\$ bundle exec rake doc

this will automatically open the index.html

Acknowledgements

This app is formerly known as **Helping Culture**, which in turn was originally conceived and inspired by Tracy Page.

This project was originally written by Shane de Silva.

It is currently maintained by the FnF org, and within it specifically

- Konstantin Gredeskoul for any application issues,
- Mike Matera for any issues related to deployment to the Google Public Cloud.
- Matt Levy for development, coordination and project management.

Please use labels to tag any reported issues.
